

CA267 Week 3 - Lab Materials – Answers:

Beech Hill Library Project:

Task 1.

Make a list of these stakeholders and explain why they will need to be consulted on the project.

1. Teachers = teachers will be one of the primary users of the software
2. Students = students will be one of the primary users of the software
3. Parents = parents will be the primary users of the software
4. Librarians = librarians would manage content of the library
5. School IT support = admins of the IT systems in the school should have a greater technical understanding of the software to be able to manage it and help student body and teachers
6. Software developers = developers will be responsible for making all of the software
7. Legal regulation authority = we need to make sure that the software complies with all the laws and regulations, especially because the software is meant to serve an educational institution

Task 2.

Having consulted with the stakeholders that you have identified, list the assumptions, risks and dependencies that you have made regarding the project. Also, explain what is in scope and out of scope for the project.

- Software needs to be intuitive since it will be used by a lot of people, including older teachers, and younger students
- Software needs to take into account that some primary users have disabilities (like poor eyesight, dyslexia etc.)
- Software needs to be compatible with any device (for example phones, laptops, computers, older and newer versions)
- We are assuming that all users have a device to use the software

Scope of the software:

Task 5.

As the Test Analyst, you have worked with the Business Analyst to identify the requirements for all the remaining main functions of the Beech Hill Library System and development of the system is underway and the system will be available for test soon. You are aware that there will be bugs in the system. Work with the Business Analyst to develop an approach to finding the bugs in the system. Explain which parts of the system you want to work on and why

To find the bugs in the system, we would need to first focus on the most critical parts

1. Logging into the system = log in function must be checked for bugs because without account management the system cannot be accessed and the system cannot keep track of who is loaning the book
2. Searching for a book = without the proper search engine within the system, users wouldn't find a specific book they're looking for
3. Loaning a book = this is the main function of the library so we have to make sure that it has no bugs
4. Returning a book = this is essential for keeping inventory and being able to get the book back after it was loaned

Task 6.

Your boss in *TestABC* has contacted you to ask how long the testing phase will take for the Beech Hill Project. How will you go about estimating how long the test phase will take and what things do you think are the most important to consider? Why is this task difficult to do?

- A week per most critical part and two weeks for any unexpected issue while testing
- The most important things to consider when determining the estimated time of testing is the number of the critical parts and their complexity
- It's difficult to estimate the time of testing because any sort of error can come up, and depending on the criticality, it can take a significant amount of time to be corrected and re-tested

Task 7.

As Test Analyst and Business Analyst you are working together to plan the User Acceptance Testing phase in detail. Work together to identify what exit criteria should apply to this phase of testing. From the exit criteria that you have identified, which could be relaxed if the project goes off course.

- All main functions pass the tests

- User acceptance
- The speed of system (can be relaxed if the project goes off course)
- Secondary services such as keeping track of users history pass the tests (can be relaxed)

Task 8.

Types of defects you might find during testing

- Unreasonably rejected valid emails and passwords
- Accepted invalid emails and passwords

Defects to fix first would be ones that are concerned with user (sensitive information) and system security (hacking prevention), as well as the main functionality of the system.

The process to do this would be to list all of the defects we found and determine the level of severity. After this, we can report the defect in detail, including the test result, and send it to the corresponding developer.
